27

28 **Abstract**

29 We estimated monthly air–sea CO₂ fluxes in the Arctic Ocean and its adjacent seas

30 north of 60° N from 1997 to 2014, after mapping partial pressure of CO₂ in the surface

31 water ($p\text{CO}_{2w}$) using a self-organizing map (SOM) technique incorporating

32 chlorophyll-a concentration (Chl-a), sea surface temperature, sea surface salinity, sea ice

33 concentration, atmospheric CO₂ mixing ratio, and geographical position. The overall

34 relationship between $p\text{CO}_{2w}$ and Chl-a is negative in most regions when Chl-a ≤ 1 mg

35 m^{-3} , whereas there is no significant relationship when Chl-a > 1 mg m^{-3} . In the Kara

36 Sea and the East Siberian Sea and the Bering Strait, however, the relationship is

37 typically positive in summer. The addition of Chl-a as a parameter in the SOM process
38 enabled us to improve the estimate of $p\text{CO}_{2w}$ via better representation of its decline in
39 spring, which resulted from biologically mediated $p\text{CO}_{2w}$ reduction. Mainly as a result
40 of the inclusion of Chl-a, the uncertainty in the CO_2 flux estimate was reduced, and a
41 net annual Arctic Ocean CO_2 uptake of $180 \pm 130 \text{ TgC y}^{-1}$ was determined to be
42 significant.

43

44 **1. Introduction**

45 The Arctic Ocean and its adjacent seas (Fig. 1) are thought to act as a sink for
46 atmospheric CO_2 because of the high solubility of CO_2 in its low-temperature waters,
47 combined with its extensive primary production during the summer season (Bates and
48 Mathis, 2009). The Arctic Ocean and its adjacent seas consist of complicated subregions
49 that include continental shelves, central basins, and sea-ice-covered areas. Therefore,
50 the surface partial pressure of CO_2 ($p\text{CO}_{2w}$) distribution is not only affected by ocean
51 heat loss and gain, and biological production and respiration, but also by sea-ice
52 formation and melting, river discharge, and shelf–basin interactions (cf. Bates and
53 Mathis, 2009). CO_2 measurements are sparse in this very heterogeneous area (Fig. 2),
54 and hence air–sea CO_2 flux estimates in the Arctic have shown poor agreement

55 (Schuster et al., 2013).

56 As global warming progresses, melting of sea ice will increase the area of open water
57 and enhance the potential for uptake of atmospheric CO₂ (e.g., Bates et al., 2006; Gao et
58 al., 2012). However, other processes will occur simultaneously, some of which could
59 suppress CO₂ uptake. For example, increasing seawater temperatures, declining buffer
60 capacity due to the freshening of Arctic surface water by increased river runoff and
61 ice-melting, and increased vertical mixing supplying high-CO₂ water to the surface
62 (Bates and Mathis, 2009; Cai et al., 2010; Chierici et al., 2011; Else et al., 2013; Bates
63 et al. 2014; Fransson et al., 2017), will all result in a tendency for reduced uptake. The
64 combined effect of all these processes on ocean CO₂ uptake has not yet been clarified
65 for the Arctic.

66 Yasunaka et al. (2016) successfully prepared monthly maps of air–sea CO₂ fluxes
67 from 1997 to 2013 for the Arctic north of 60° N by applying, for the first time, a
68 self-organizing map (SOM) technique to map $p\text{CO}_{2w}$ in the Arctic Ocean. The
69 advantage of the SOM technique is its ability to empirically determine relationships
70 among variables without making any a priori assumptions (e.g., what types of
71 regression functions are applicable, and for which sub-regions the same regression
72 function can be adopted). The SOM technique has been shown to reproduce the

73 distribution of $p\text{CO}_{2w}$ from unevenly distributed observations better than multiple
74 regression methods (Lefèvre et al., 2005; Telszewski et al., 2009). The uncertainty of
75 the CO_2 flux estimated by Yasunaka et al. (2016), however, was large ($\pm 3.4\text{--}4.6$ mmol
76 $\text{m}^{-2} \text{d}^{-1}$), and the estimated CO_2 uptake in the Arctic Ocean was smaller than the
77 uncertainty ($180 \pm 210 \text{ TgC y}^{-1}$). One possible reason for the large uncertainties is that
78 the effect of biological processes on explaining the variability was not included among
79 the parameters used in the SOM process, which could lead to an underestimation of the
80 seasonal amplitude of $p\text{CO}_{2w}$.

81 Several studies have estimated chlorophyll-a concentrations (Chl-a) in the Arctic
82 from satellite remote sensing reflectance (Rrs) (e.g. Arrigo and Dijken, 2004; Cota et al.,
83 2004). Perrette et al. (2011) showed that satellite-derived Chl-a successfully captured a
84 phytoplankton bloom in the ice-edge region. Changes in the seasonal cycle of Chl-a
85 have also been observed and are likely a consequence of the recent sea-ice loss in the
86 Arctic (Ardyna et al., 2014). Measurements in several areas of the Arctic show that the
87 relationship between $p\text{CO}_{2w}$ and Chl-a is typically negative, as expected (Gao et al.,
88 2012; Ulfsbo et al., 2014). Exceptions do occur, however, in the coastal regions, where
89 the relationship is positive (Mucci et al., 2010). Chierici et al. (2009) produced $p\text{CO}_{2w}$
90 algorithms for the subpolar North Atlantic and found that the inclusion of Chl-a

91 improved the fit substantially during the period from May to October.

92 In the present study, we examined the relationship between $p\text{CO}_{2w}$ and Chl-a in the
93 Arctic Ocean and its adjacent seas, and presented monthly air–sea CO_2 flux maps for
94 regions north of 60° N using a SOM technique similar to that of Yasunaka et al. (2016),
95 and with Chl-a added to the SOM process.

96

97 **2. Data**

98 2.1. $p\text{CO}_{2w}$ measurements

99 We used $p\text{CO}_{2w}$ observations (converted from the fugacity of CO_2 values; a correction
100 of $<1\%$) from the Surface Ocean CO_2 Atlas version 4 (SOCATv4; Bakker et al., 2016;
101 <http://www.socat.info/>; 1,983,799 data from $>60^\circ$ N), and from the Global Surface
102 $p\text{CO}_2$ Database Version 2014 (LDEOv2014; Takahashi et al., 2015;
103 http://cdiac.ornl.gov/oceans/LDEO_Underway_Database/; 302,150 data from $>60^\circ$ N).
104 Duplicate data points were eliminated; the SOCAT versions of these duplicates were
105 used, except for the data obtained from onboard the USCGC *Healy* as these have been
106 reanalyzed by Takahashi et al. (2015). Altogether 200,409 duplicates were removed. We
107 also used shipboard $p\text{CO}_{2w}$ data obtained during cruises of the R/V *Mirai* of the Japan
108 Agency for Marine-Earth Science and Technology (JAMSTEC) that have not yet been

109 included in SOCATv4 or LDEOv2014 (cruises MR09_03, MR10_05, MR12_E03, and
110 MR13_06; <http://www.godac.jamstec.go.jp/darwin/e>; 95,725 data from >60° N). In total,
111 we used 2,181,265 $p\text{CO}_{2w}$ data, 33 % more than used by Yasunaka et al. (2016).

112 To improve the data coverage, especially for the ice-covered regions, we also used
113 2166 $p\text{CO}_{2w}$ values calculated from dissolved inorganic carbon and total alkalinity data
114 extracted from the Global Ocean Data Analysis Project version 2 (GLODAPv2; Key et
115 al., 2015; Olsen et al., 2016; <http://cdiac.ornl.gov/oceans/GLODAPv2/>). 90% of these
116 data were obtained at cruises without available underway $p\text{CO}_{2w}$ data. We extracted
117 values of samples obtained from water depths shallower than 10 m, or the shallowest
118 values from the upper 30 m of each cast if there were no values from above 10 m. We
119 used the CO2SYS program (Lewis and Wallace, 1998; van Heuven et al., 2009) and the
120 dissociation constants reported by Lueker et al. (2000) and Dickson (1990) for the
121 calculation. This resulted in 94 % more calculated $p\text{CO}_{2w}$ values than used by Yasunaka
122 et al. (2016).

123 The availability of $p\text{CO}_{2w}$ data (directly measured and calculated) varied spatially and
124 temporally (Fig. 2). Most of the available data are from the subpolar North Atlantic, the
125 Greenland Sea, the Norwegian Sea, the Barents Sea, and the Chukchi Sea while much
126 less data are available for the Kara Sea, the Laptev Sea, the East Siberian Sea, and the

127 Eurasian Basin. The number of $p\text{CO}_{2w}$ data strongly increases after 2005, but there is
128 also a substantial number of data from before 2004.

129

130 2.2. Other data

131 To calculate Chl-a, we used merged Rrs data from multi-ocean color sensors processed
132 and distributed by the GlobColour Project (Maritorena et al., 2010;
133 <http://hermes.acri.fr/index.php?class=archive>). For compatibility with the
134 spatio-temporal resolution of the gridded $p\text{CO}_{2w}$ data (see Sect. 3.3), we selected
135 monthly mean Rrs data with a spatial resolution of $1^\circ \times 1^\circ$.

136 Sea surface temperature (SST) data were extracted from the National Oceanic and
137 Atmospheric Administration (NOAA) Optimum Interpolation SST Version 2 (Reynolds
138 et al., 2002; <http://www.esrl.noaa.gov/psd/data/gridded/data.noaa.oisst.v2.html>). These
139 data are provided at a resolution of 1° (latitude) \times 1° (longitude) \times 1 month. The sea
140 surface salinity (SSS) data were retrieved from the Polar Science Center Hydrographic
141 Climatology version 3.0, which also has a resolution of $1^\circ \times 1^\circ \times$ 1 month (Steele et al.,
142 2001; http://psc.apl.washington.edu/nonwp_projects/PHC/Climatology.html). The sea
143 ice concentration (SIC) data were obtained from the NOAA/National Snow and Ice
144 Data Center Climate Data Record of Passive Microwave Sea Ice Concentration version

145 2, which has a resolution of $25 \text{ km} \times 25 \text{ km} \times 1 \text{ month}$ (Meier et al., 2013;
146 <http://nsidc.org/data/G02202>). These data were averaged into $1^\circ \times 1^\circ \times 1 \text{ month}$
147 grid-cells. Zonal mean data for the atmospheric CO_2 mixing ratio ($x\text{CO}_{2a}$) were
148 retrieved from the NOAA Greenhouse Gas Marine Boundary Layer Reference data
149 product (Conway et al., 1994; <http://www.esrl.noaa.gov/gmd/ccgg/mbl/index.html>) and
150 were interpolated into $1^\circ \times 1^\circ \times 1 \text{ month}$ grid-cells. We used monthly sea level pressure
151 data and the 6-hourly 10-m wind speeds from the U.S. National Centers for
152 Environmental Prediction–Department of Energy Reanalysis 2 (NCEP 2) (Kanamitsu et
153 al., 2002; <http://www.esrl.noaa.gov/psd/data/gridded/data.ncep.reanalysis2.html>). We
154 also used the 6-hourly 10-m wind speeds from the U.S. National Centers for
155 Atmospheric Prediction and the National Center for Atmospheric Research Reanalysis 1
156 (NCEP1) (Kalnay et al., 1996;
157 <https://www.esrl.noaa.gov/psd/data/gridded/data.ncep.reanalysis.html>) to optimize the
158 gas transfer velocity.

159 Surface nitrate measurements were extracted from GLODAPv2 (Key et al., 2015;
160 Olsen et al., 2016) and the World Ocean Database 2013 (Boyer et al., 2013).

161

162 3. Methods

163 3.1. Calculation of chlorophyll-a concentrations

164 We calculated Chl-a from Rrs by using the Arctic algorithm developed by Cota et al.
165 (2004). Several assessments have shown that the Arctic algorithm by Cota et al. (2004)
166 has a large uncertainty (e.g., Matsuoka et al., 2007; Lewis et al., 2016), so we evaluated
167 the sensitivity of our results to this choice by using two other algorithms for Chl-a: the
168 standard algorithm, of O'Reilly et al. (1998), and the coastal algorithm, of Tassan
169 (1994).

170 To ensure that we were working with Rrs relatively unaffected by suspended
171 sediments and colored dissolved organic matter, we masked the Chl-a data following the
172 method of Siswanto et al. (2013). We plotted the Rrs spectral slope between 412 and
173 555 nm ($R_{rs555-412 \text{ slope}}$; $\text{sr}^{-1} \text{ nm}^{-1}$) against logarithmically transformed Chl-a. We then
174 defined a boundary line separating phytoplankton-dominated grid-cells ($R_{rs555-412 \text{ slope}} <$
175 boundary value) from potentially non-phytoplankton-dominated grid-cells ($R_{rs555-412}$
176 $\text{ slope} \geq$ boundary value):

177

$$178 \quad R_{rs555-412 \text{ slope}} = -0.000003 \{\log(\text{Chl-a})\}^2 + 0.00002 \{\log(\text{Chl-a})\} + 0.00006. \quad (1)$$

179

180 Grid-cells were considered invalid and masked out if 1) $R_{rs555-412 \text{ slope}} \geq$ boundary value,

181 and 2) R_{rs} at 555nm ($R_{rs555} > 0.01 \text{ sr}^{-1}$) (or normalized water-leaving radiance $> 2 \text{ mW}$

182 $\text{cm}^{-2} \mu\text{m}^{-1} \text{sr}^{-1}$; see Siswanto et al., 2011; Moore et al., 2012).

183 The criteria described in the previous paragraph could mask out grid-cells having

184 coccolithophore blooms, which are sometimes observed in the Arctic Ocean (e.g.,

185 Smyth et al., 2004), as they also have $R_{rs555} > 0.01 \text{ sr}^{-1}$ (Moore et al., 2012). Unlike

186 waters dominated by non-phytoplankton particles, whose R_{rs} spectral shape peaks at

187 555 nm, the R_{rs} spectral shape of waters with coccolithophore blooms peaks at 490 or

188 510 nm (see Iida et al., 2002; Moore et al., 2012). Therefore, grid-cells with R_{rs} spectral

189 peaks at 490 or 510 nm (already classified using the criteria of R_{rs} at 490nm ($R_{rs490} >$

190 R_{rs} at 443nm (R_{rs443}) and R_{rs} at 510nm ($R_{rs510} > R_{rs555}$) were considered as

191 coccolithophore grid-cells, and were re-included.

192

193 3.2. Chlorophyll-a interpolation

194 Chl-a values calculated from R_{rs} are often missing because of cloud cover, low angle of

195 sunlight, or sea ice. For the period and area analyzed here, data are missing for 86 % of

196 the space and time grid-cells. Because $p\text{CO}_{2w}$ mapping requires a complete Chl-a field

197 without missing values, we interpolated Chl-a data as follows. 1) Chl-a was set to 0.01

198 mg m^{-3} (minimum value of Chl-a) in high-latitude regions in winter when there was no

199 light (north of 80° N in December and January, and north of 88° N in November and
200 February). 2) Whenever SIC was greater than 99 %, Chl-a was set to 0.01 mg m⁻³ (full
201 ice coverage, thus minimum Chl-a). We chose the strict criterion of SIC > 99 % because
202 weak but significant primary production has been found to occur under the sea ice in
203 regions with SIC around 90 % (Gosselin et al., 1997; Ulfsbo et al., 2014; Assmy et al.,
204 2017). 3) The remaining grid-cells with missing data were filled, wherever possible,
205 using Chl-a averaged over ±1° latitude and ±1° longitude; this mainly compensated for
206 missing Chl-a values as a result of cloud cover. 4) Parts of the remaining missing Chl-a
207 values, mainly for the pre-satellite period of January–August 1997, were set to the
208 monthly climatology Chl-a values based on the 18-year monthly mean from 1997 to
209 2014. 5) The final remaining missing Chl-a data, mainly for the marginal sea-ice zone,
210 were generated by linear interpolation using surrounding data. With each interpolation
211 step the number of the grid-cells with missing data decreased; 23 % of the grid-cells
212 without Chl-a data were filled by the first step, and in the same manner the subsequent
213 steps provided data for 12, 8, 5, and 52 %, respectively.

214

215 3.3. Gridding procedure for pCO₂ data

216 The individual pCO_{2w} data were gridded to 1° × 1° × 1 month grid-cells covering the

217 years from 1997 to 2014 using the same procedure as Yasunaka et al. (2016). As
218 reference values, we calculated the long-term mean (i.e., the climatology) and its
219 standard deviation for a window size of $\pm 5^\circ$ of latitude, $\pm 30^\circ$ of longitude, and ± 2
220 months (regardless of the year) for each $1^\circ \times 1^\circ \times 1$ month grid-cell. We then eliminated
221 data in each grid-cell that differed by more than three standard deviations from the
222 climatology. We next recalculated the climatology and its standard deviation using a
223 smaller window size of $\pm 2^\circ$ of latitude, $\pm 10^\circ$ of longitude, and ± 1 month (regardless of
224 the year) for each $1^\circ \times 1^\circ \times 1$ month grid-cell. We again eliminated data that differed
225 from the climatology by more than three standard deviations.

226 This procedure identified in total about 0.5 % of the data as extreme or erroneous
227 values. These excluded values are randomly distributed in time and space. The
228 remaining observations were binned into $1^\circ \times 1^\circ \times 1$ month grid-cells for each year
229 from 1997 to 2014. Although some studies have used $p\text{CO}_{2w}$ normalized to a certain
230 year, based on the assumption of a constant rate of increase for $p\text{CO}_{2w}$ (e.g., Takahashi
231 et al., 2009), we used “non-normalized” $p\text{CO}_{2w}$ values from all years; therefore, $p\text{CO}_{2w}$
232 can increase both non-linearly in time and non-uniformly in space. We believe that this
233 better represents the real variability and trends of $p\text{CO}_{2w}$.

234

235 3.4. $p\text{CO}_2$ estimation using a self-organizing map

236 We estimated $p\text{CO}_{2w}$ by the SOM technique used by Yasunaka et al. (2016), with the
237 exception that Chl-a was added as a parameter to train the SOM (a “training parameter”)
238 in addition to SST, SSS, SIC, $x\text{CO}_{2a}$, and geographical position X ($=\sin[\text{latitude}] \times$
239 $\cos[\text{longitude}]$) and Y ($=\sin[\text{latitude}] \times \sin[\text{longitude}]$). Chl-a, SST, SSS, and SIC are
240 closely related to processes causing variation in $p\text{CO}_{2w}$, such as primary production,
241 warming/cooling, mixing, and freshwater input, whereas $x\text{CO}_{2a}$ is related to seasonal
242 changes from terrestrial CO_2 uptake and release, and the anthropogenic CO_2 increase.
243 Thus, Chl-a, SST, SSS, and SIC represent spatio-temporal variability at seasonal to
244 interannual time-scales, and $x\text{CO}_{2a}$ acts as a temporal variable representing the seasonal
245 cycle and the long-term trend. The use of geographical position as a training parameter
246 can prevent a systematic spatial bias (Yasunaka et al., 2014).

247 Briefly, the SOM technique was implemented as follows: first, the approximately one
248 million $1^\circ \times 1^\circ \times 1$ month grid-cells in the analysis region and period were assigned to
249 5000 groups, which are called “neurons”, of the SOM by using the training parameters.
250 Second, each neuron was labeled, whenever possible, with the $p\text{CO}_{2w}$ value observed at
251 the grid-cell at which Chl-a, SST, SSS, SIC, $x\text{CO}_{2a}$, and X and Y values were most
252 similar to those of the neuron. Finally, each grid-cell in the analysis region and period

253 was assigned the $p\text{CO}_{2w}$ value of the neuron whose Chl-a, SST, SSS, SIC, $x\text{CO}_{2a}$, and X
254 and Y values were most similar to those at that grid-cell. If the most similar neuron was
255 not labeled with a $p\text{CO}_{2w}$ value, then the $p\text{CO}_{2w}$ value of the neuron that was most
256 similar *and* labeled was used. A detailed procedure can be found in Telzewski et al.
257 (2009) and Nakaoka et al. (2013).

258

259 3.5. Calculation of air–sea CO_2 fluxes

260 We calculated monthly air–sea CO_2 flux (F) values from the $p\text{CO}_{2w}$ values estimated in
261 Sect. 3.4 by using the bulk formula:

262

$$263 \quad F = kL(p\text{CO}_{2w} - p\text{CO}_{2a}), \quad (2)$$

264

265 where k is the gas transfer velocity and L is the solubility of CO_2 . The solubility of CO_2
266 (L) was calculated as a function of SST and SSS (Weiss, 1974). We converted the
267 interpolated NOAA marine boundary layer $x\text{CO}_{2a}$ data (Sect. 2.2) to $p\text{CO}_{2a}$ by using
268 monthly sea-level pressure data and the water-vapor saturation pressure calculated from
269 monthly SST and SSS (Murray, 1967).

270 The gas transfer velocity k was calculated by using the formula of Sweeney et al.

271 (2007):

272

$$273 \quad k = 0.19 (\text{Sc}/660)^{-0.5} \langle W_{\text{NCEP2}}^2 \rangle, \quad (3)$$

274

275 where Sc is the Schmidt number of CO₂ in seawater at a given SST and was calculated

276 according to Wanninkhof (2014), “<>” denotes the monthly mean, and $\langle W_{\text{NCEP2}}^2 \rangle$ is

277 the monthly mean of the second moment of the NCEP2 6-hourly wind speed. The

278 coefficient 0.19, which is the global average of $0.27 \langle W_{\text{NCEP1}}^2 \rangle / \langle W_{\text{NCEP2}}^2 \rangle$, is based on

279 the one determined by Sweeney et al. (2007) but optimized for NCEP2 winds following

280 the same method as Schuster et al. (2013) and Wanninkhof et al. (2013).

281 The suppression of gas exchange by sea ice was accounted for by correcting the air–

282 sea CO₂ fluxes using the parameterization presented by Loose et al. (2009); the flux is

283 proportional to $(1-\text{SIC})^{0.4}$. The SIC effect used in this study is consistent with the linear

284 SIC effect derived from another approach by Takahashi et al. (2009) and Butterworth

285 and Miller (2016) within the uncertainty of 30%. Following Bates et al. (2006), in the

286 regions with SIC > 99 %, we used SIC = 99 % to allow for non-negligible rates of air–

287 sea CO₂ exchange through leads, fractures, and brine channels (Semiletov et al., 2004;

288 Fransson et al., 2017).

289

290 **4. Uncertainty**

291 4.1. Uncertainty in chlorophyll-a concentration data

292 Figure 3 shows original and interpolated Chl-a for 2012 as an example. Most

293 interpolated Chl-a data are low concentrations because of high SIC and lack of daylight.

294 Overall, the interpolated Chl-a data seem to fit well with the original data.

295 To evaluate our choice of Chl-a algorithm (i.e. the Arctic algorithm of Cota et al.,

296 2004), we compared its calculated Chl-a values with those determined by using the

297 standard algorithm of O'Reilly et al. (1998) and the coastal algorithm of Tassan (1994).

298 The root mean square difference (RMSD) and correlation coefficient (r) between the

299 original (i.e. non-interpolated) Chl-a values determined with the Arctic algorithm and

300 the standard algorithm are 0.80 mg m^{-3} and 0.90, respectively, and between those

301 determined with the Arctic algorithm and the coastal algorithm are 0.81 mg m^{-3} and

302 0.87, respectively (Table 1). For the interpolated Chl-a values, they are 0.37 mg m^{-3} and

303 0.92 , and 0.48 mg m^{-3} and 0.86, respectively. The lower RMSD results from the fact

304 that most of the interpolated Chl-a values represent low concentrations. The $p\text{CO}_{2w}$ and

305 CO_2 fluxes determined using Chl-a from any of these algorithms as input to the SOM

306 are consistent within uncertainties of the $p\text{CO}_{2w}$ and CO_2 flux estimates (see Sects. 4.2

307 and 4.3 below).

308 To validate our Chl-a interpolation, we repeated the interpolation after randomly
309 eliminating 10 % of the satellite Chl-a values. We then used the eliminated original
310 Chl-a data as independent data for validation. The RMSD and correlation coefficient
311 between the interpolated and the independent original Chl-a data are 0.90 mg m^{-3} and
312 0.80 , respectively. It means the interpolated Chl-a generally reproduced the Chl-a
313 concentrations, and therefore is a meaningful parameter in the SOM process.

314

315 4.2. Uncertainty of $p\text{CO}_{2w}$ mapping

316 Both observed and estimated $p\text{CO}_{2w}$ tended to be high in the subpolar North Atlantic,
317 the Laptev Sea, and the Canada Basin, and low in the Greenland Sea and the Barents
318 Sea (Figs. 4a and 4b; Note that the spatial change depicted in Figs. 4a and 4b include
319 differences in the observed seasons depending on the regions). However, the east–west
320 contrast in the Bering Sea and the contrast between the Canada Basin and the Chukchi
321 Sea are weaker in our estimates than those in the observations, and mean bias and
322 RMSD are relatively large in those areas (Figs. 5a and 5b). The temporal changes in the
323 observed and estimated $p\text{CO}_{2w}$ are in phase, although the variability of the estimated
324 values is somewhat suppressed compared to that of the observed data (Fig. 4c; Note that

325 the temporal change depicted in Fig. 4c includes changes in the positions of the

326 observation points). Mean bias and RMSD show no long-term change (Fig. 5c).

327 The correlation coefficient between estimated and observed $p\text{CO}_{2w}$ values is 0.82,

328 and the RMSD is 30 μatm , which is 9 % of the average and 58 % of the standard

329 deviation of the observed $p\text{CO}_{2w}$ values (a performance level of 58 % is categorized as

330 “good” by Maréchal [2004]). The differences between the estimated and observed

331 values stem not only from the estimation error but also from the error of the gridded

332 observation data. The uncertainty of the $p\text{CO}_{2w}$ measurements is 2–5 μatm (Bakker et

333 al., 2014), the uncertainty of the $p\text{CO}_{2w}$ values calculated from dissolved inorganic

334 carbon and total alkalinity can be up to 14 μatm (Lueker et al., 2000), and the sampling

335 error of the gridded $p\text{CO}_{2w}$ observation data was deduced from the standard errors of

336 monthly observed $p\text{CO}_{2w}$ in the $1^\circ \times 1^\circ$ grid-cells to be 7 μatm (Yasunaka et al., 2016).

337 To validate our estimated $p\text{CO}_{2w}$ values for periods and regions without any observed

338 data, we repeated the mapping experiments after systematically excluding some of the

339 observed $p\text{CO}_{2w}$ data when labeling the neurons; four experiments were carried out, by

340 excluding data (1) for 1997–2004, (2) for January to April, (3) from north of 80°N , and

341 (4) from the Laptev Sea ($90^\circ\text{E} - 150^\circ\text{E}$), where there are only a few $p\text{CO}_{2w}$ observations.

342 The RMSDs between the estimates and the excluded observations are 54 μatm on

343 average, which is 1.8 times the RMSDs of the estimates based on all observations.

344 Hence the uncertainty in $p\text{CO}_{2w}$ might be as large as 16 % in regions and periods

345 without data.

346

347 4.3. Uncertainty of CO_2 flux estimates

348 Signorini and McClain (2009) estimated the uncertainty of the CO_2 flux resulting from

349 uncertainties in the gas exchange parameterization to be 36 %, and that resulting from

350 uncertainties in the wind data to be 11 %. The uncertainty for SIC is 5 % (Cavaliere et

351 al., 1984; Gloersen et al., 1993; Peng et al., 2013). The standard error of the sea-ice

352 effect on gas exchange was estimated to about 30 % by Loose et al. (2009). The

353 uncertainty of $p\text{CO}_{2a}$ is about $0.5 \mu\text{atm}$

354 (<http://www.esrl.noaa.gov/gmd/ccgg/mbl/mbl.html>), and that of $p\text{CO}_{2w}$ was $30 \mu\text{atm}$

355 (Sect. 4.2); therefore, we estimated the uncertainty of $\Delta p\text{CO}_2$ ($=p\text{CO}_{2w} - p\text{CO}_{2a}$) to be

356 34 % (average $\Delta p\text{CO}_2$ in the analysis domain and period was $-89 \mu\text{atm}$). The overall

357 uncertainty of the estimated CO_2 fluxes is 59 % ($[0.36^2 + 0.11^2 + 0.05^2 + 0.3^2 +$

358 $0.34^2]^{1/2}$) in the sea-ice covered region and 51 % ($[0.36^2 + 0.11^2 + 0.05^2 + 0.34^2]^{1/2}$) in

359 the ice-free region. In regions and periods without any observed data, where the

360 uncertainty in $p\text{CO}_{2w}$ is $54 \mu\text{atm}$ and the uncertainty of the $\Delta p\text{CO}_2$ estimates can be as

361 high as 61 %, the uncertainty is 78 % ($[0.36^2 + 0.11^2 + 0.05^2 + 0.3^2 + 0.61^2]^{1/2}$) in
362 sea-ice covered regions, and 72 % ($[0.36^2 + 0.11^2 + 0.05^2 + 0.61^2]^{1/2}$) in ice-free regions.
363 The average of the estimated CO₂ flux in the analysis domain and period is 4.8 mmol
364 m⁻² d⁻¹; hence the uncertainty of the CO₂ flux estimate corresponds to 2.8 mmol m⁻² d⁻¹
365 in sea-ice covered regions and 2.4 mmol m⁻² d⁻¹ in ice-free regions. In regions and
366 periods without observed data, the uncertainty corresponds to 3.7 mmol m⁻² d⁻¹ in the
367 sea-ice covered region and 3.5 mmol m⁻² d⁻¹ in ice-free regions.

368

369 **5. Results and discussion**

370 5.1. Relationship between *p*CO₂ and chlorophyll-a

371 We compared the observed *p*CO_{2w} and the original non-interpolated Chl-a in spring
372 (March–May) and summer (July–September) (Fig. 6a and b). In spring, when much of
373 the Arctic Ocean is ice-covered, Chl-a is high in the Barents Sea and the Bering Strait
374 (>1 mg m⁻³). In summer, when the ice cover is less extensive, Chl-a is high in the
375 Chukchi Sea, the Kara Sea, the Laptev Sea, and the East Siberian Sea (>1 mg m⁻³) and
376 especially high in the coastal region (>2 mg m⁻³). *p*CO_{2w} is high in the Norwegian Sea
377 in spring; and also high in the Kara Sea, the Laptev Sea and the Canada Basin during
378 summer (>300 μatm). On the other hand, it is lower in the Chukchi Sea, Bering Strait

379 area and the sea-ice edge region of the Eurasian Basin in summer ($<300 \mu\text{atm}$). The
380 overall relationship between $p\text{CO}_{2\text{w}}$ and Chl-a is negative where $\text{Chl-a} \leq 1 \text{ mg m}^{-3}$ (70%
381 of all the data; correlation coefficient $r = -0.36$, $P < 0.01$), but there is no significant
382 relationship where $\text{Chl-a} > 1 \text{ mg m}^{-3}$ (Fig. 7), as also shown by Olsen et al. (2008) in the
383 subpolar North Atlantic. That is probably because high Chl-a usually appeared in the
384 coastal region (Fig. 6b) which are affected by the river runoff.

385 To determine the spatial variability of the relationship between $p\text{CO}_{2\text{w}}$ and Chl-a, we
386 calculated the correlation coefficients between $p\text{CO}_{2\text{w}}$ and Chl-a in a window of $\pm 5^\circ$ of
387 latitude, and $\pm 30^\circ$ of longitude for each monthly $1^\circ \times 1^\circ$ grid-cell (Fig. 6d). We found
388 negative relationships between $p\text{CO}_{2\text{w}}$ and Chl-a in the Greenland/Norwegian Seas and
389 the Canada Basin. In the Greenland/Norwegian Seas, the relationship between $p\text{CO}_{2\text{w}}$
390 and Chl-a is strongly negative ($r < -0.4$) in spring and weakly negative ($-0.4 < r < 0$) in
391 summer. Chl-a there is higher in summer than in spring, whereas nutrient concentrations
392 are high in spring and low in summer (Fig. 6c). These correlations suggest that primary
393 production draws down the $p\text{CO}_{2\text{w}}$ in spring, whereas in summer the primary production
394 mostly depends on regenerated nutrients (Harrison and Cota, 1991) and the net CO_2
395 consumption is small, as also reported for the subpolar North Atlantic (Olsen et al.,
396 2008). In the eastern Barents Sea, the Kara Sea and the East Siberian Sea, and the

397 Bering Strait, the relationships are positive because of water with high $p\text{CO}_{2\text{w}}$ and Chl-a
398 in the coastal region subjected to river discharge (Murata, 2006; Semiletov et al., 2007;
399 Anderson et al., 2009; Manizza et al., 2011). In the Chukchi Sea, the relationship is
400 weak ($-0.2 < r < 0.2$), probably because the relationship is on smaller spatial and
401 temporal scales than those represented by the window size used here, as shown by
402 Mucci et al. (2010). Calcifying plankton bloom would also weaken the correlation since
403 it will affect the $p\text{CO}_{2\text{w}}$ in the different way (Shutler et al., 2013; Fransson et al., 2017).

404

405 5.2. Spatiotemporal CO_2 flux variability

406 The 18-year annual mean CO_2 flux distribution shows that all areas of the Arctic
407 Ocean and its adjacent seas were net CO_2 sinks over the time period that we
408 investigated (Fig. 8). The annual CO_2 influx to the ocean is strong in the
409 Greenland/Norwegian Seas ($9 \pm 3 \text{ mmol m}^{-2} \text{ d}^{-1}$; 18-year annual mean \pm uncertainty
410 averaged over the area shown in Fig. 1), the Barents Sea ($10 \pm 3 \text{ mmol m}^{-2} \text{ d}^{-1}$), and the
411 Chukchi Sea ($5 \pm 3 \text{ mmol m}^{-2} \text{ d}^{-1}$). In contrast, influx is weak and not statistically
412 significantly different from zero in the Eurasian Basin and the Canada Basin, or in the
413 Laptev Sea and the East Siberian Sea. Our annual CO_2 flux estimates are consistent with
414 those reported by Yasunaka et al. (2016) and other previous studies (Bates and Mathis,

415 2009, and references therein). The estimated 18-year average CO₂ influx to the Arctic
416 Ocean is $5 \pm 3 \text{ mmol m}^{-2} \text{ d}^{-1}$, equivalent to an uptake of $180 \pm 130 \text{ TgC y}^{-1}$ for the
417 ocean area north of 65° N, excluding the Greenland/Norwegian Seas and Baffin Bay
418 ($10.7 \times 10^6 \text{ km}^2$; see Fig. 1). This is within the range of other estimates ($81\text{--}199 \text{ TgC y}^{-1}$;
419 ¹; Bates and Mathis, 2009).

420 The CO₂ influxes to the Greenland/Norwegian Seas, the Barents Sea, and the
421 Chukchi Sea are strongest in October ($>10 \text{ mmol m}^{-2} \text{ d}^{-1}$; Fig. 9), when the winds
422 strengthen with the approach of winter and the SIC and $p\text{CO}_{2w}$ are still as low as in the
423 summer. The total CO₂ influx to the Arctic Ocean is also strongest in October. The CO₂
424 influx shows a secondary maximum in February in the Greenland/Norwegian Seas and
425 the Barents Sea because the strongest winds occur in that month (not shown).

426 The CO₂ influx has been increasing in the Greenland Sea and northern Barents Sea,
427 and decreasing in the Chukchi Sea and southern Barents Sea (Fig. 10). The CO₂ flux
428 trend corresponds well with the $\Delta p\text{CO}_2$ trend, which in turn corresponds well with the
429 SST trend. High $p\text{CO}_{2w}$ ($>500 \mu\text{atm}$) has been sometimes observed in the Chukchi Sea
430 after 2010 (Hauri et al. 2013). The increasing CO₂ influx in the northern Barents Sea
431 also corresponds with the sea-ice retreat.

432

433 5.3. Impact of incorporating chlorophyll-a data in the SOM

434 To determine the impact of including Chl-a data in the SOM process, the analyses were
435 repeated without Chl-a data. The RMSD of the resulting estimated $p\text{CO}_{2w}$ values is 33
436 μatm , 3 μatm larger than the uncertainty of the estimates generated by including Chl-a
437 in the SOM. Chl-a data thus improved the $p\text{CO}_{2w}$ estimate (namely, a 10 % reduction of
438 RMSD), even though 40 % of the Chl-a data labeled with $p\text{CO}_{2w}$ observations were
439 interpolated Chl-a values. This improvement resulted mainly from an improved
440 representation of the seasonal cycle of $p\text{CO}_{2w}$ by the SOM technique, which reproduced
441 the observed cycle better when Chl-a was included (upper panels of Fig. 11).

442 The seasonal cycles of $p\text{CO}_{2w}$ estimates derived with the inclusion of Chl-a has a
443 larger amplitude than the uncertainties, whereas the uncertainties are larger than the
444 seasonal amplitude of $p\text{CO}_{2w}$ derived without Chl-a (lower panels of Fig. 11). Note that
445 the much larger seasonal amplitude in observed $p\text{CO}_{2w}$ in each region (upper panels of
446 Fig. 11) is due to the seasonal changes in the extent of the observed area: area average
447 of observed $p\text{CO}_{2w}$ in winter was obtained mostly from the data in the lower latitudes,
448 where $p\text{CO}_{2w}$ tends to be higher than that in the higher latitudes. The winter CO_2 influx
449 in the Greenland/Norwegian Seas estimated including Chl-a is about $3 \text{ mmol m}^{-2} \text{ d}^{-1}$
450 less than those calculated without using Chl-a (Fig. 9), but this difference is smaller than

451 the uncertainties. The pattern in trends is similar to that for the estimates without using
452 Chl-a (see Fig. 10 in Yasunaka et al., 2016).

453 The inclusion of Chl-a data also reduced the uncertainty of the estimated annual
454 air-sea CO₂ flux integrated over the entire Arctic Ocean. Compared to the flux estimate
455 determined by Yasunaka et al. (2016) of $180 \pm 210 \text{ TgC y}^{-1}$, the CO₂ uptake in the
456 Arctic Ocean estimated here is significant within its uncertainty ($180 \pm 130 \text{ TgC y}^{-1}$).
457 This improvement is the result of 1) the inclusion of Chl-a data in the SOM process
458 (which reduced the uncertainty by 23 %); 2) the separate uncertainty estimates for
459 ice-free and ice-covered regions (8 %); and 3) the addition of new observational $p\text{CO}_{2w}$
460 data (7 %).

461

462 **6. Conclusions**

463 By applying an SOM technique with the inclusion of Chl-a data to estimate $p\text{CO}_{2w}$, we
464 produced monthly maps of air–sea CO₂ fluxes from 1997 to 2014 for the Arctic Ocean
465 and its adjacent seas north of 60° N. The overall relationship between $p\text{CO}_{2w}$ and Chl-a
466 is negative, consistent with it being determined by primary production, but the
467 relationship depended on the season and the region. Adding Chl-a to the SOM process
468 improved representation of the seasonal cycle of $p\text{CO}_{2w}$. A major goal of the

469 carbon-cycle research community in recent years has been to reduce the uncertainty in
470 estimates of carbon reservoirs and fluxes. Our results contribute to this in that CO₂
471 uptake in the Arctic Ocean is demonstrated with high significance. The resulting
472 estimate of the annual Arctic Ocean CO₂ uptake of 180 TgC y⁻¹ is significant with an
473 uncertainty of only ± 130 TgC y⁻¹. This is a substantial improvement over earlier
474 estimates, and is due mainly to the incorporation of Chl-a data.

475 The addition of new observational data from SOCATv4 and GLODAPv2 reduced the
476 overall uncertainty in the mapped *p*CO_{2w}: a 33 % increase in the number of observations
477 induced a 7 % reduction in the uncertainty. However, there are still too few observations
478 in the Kara Sea, the Laptev Sea, the East Siberian Sea and the Eurasian Basin to
479 determine seasonal and interannual variations there. To improve our understanding of
480 the variability in air–sea CO₂ fluxes in the Arctic, it is of critical importance to obtain
481 additional ocean CO₂ measurements to fill these data gaps.

482 The monthly CO₂ flux data presented in this paper will be available at the JAMSTEC
483 website (http://www.jamstec.go.jp/res/ress/yasunaka/co2flux_v2).

484

485 **Acknowledgments**

486 We thank the many researchers and funding agencies responsible for the collection of
487 data and quality control for their contributions to SOCAT and GLODAPv2. We are
488 grateful for the use of the CO2SYS program obtained from the Carbon Dioxide
489 Information Analysis Center (<http://cdiac.ornl.gov/oceans/co2rprt.html>), and SOM
490 Toolbox Version 2 developed by the Laboratory of Information and Computer Science
491 at Helsinki University of Technology (<http://www.cis.hut.fi/projects/somtoolbox>). We
492 thank ACRI-ST, France, for developing, validating, and distributing the GlobColour
493 data used in this work. This work was financially supported by the Arctic Challenge for
494 Sustainability (ArCS) Project funded by the Ministry of Education, Culture, Sports,
495 Science and Technology, Japan. Are Olsen was supported by grants from the Norwegian
496 Research Council (Subpolar North Atlantic Climate States [SNACS] 229752 and the
497 Norwegian component of the Integrated Carbon Observation System [ICOS-Norway]
498 245927). Mario Hoppema was partly supported by the German Federal Ministry of
499 Education and Research (grant no. 01LK1224I; ICOS-D). Siv K. Lauvset acknowledges
500 support from the Norwegian Research Council (VENTILATE, 229791) and the EU
501 H2020 project AtlantOS (grant agreement no. 633211). Rik Wanninkhof and Taro
502 Takahashi acknowledge support from the Office of Oceanic and Atmospheric Research
503 (OAR) of the United States NOAA, including resources from the Ocean Observation

504 and Monitoring Division of the Climate Program Office (fund reference100007298).

Figure 1: Map of the Arctic Ocean and its adjacent seas. Gray contour lines show the 1000, 2000, 3000, and 4000 m isobaths. Blue lines show the 17-year annual mean position of the ice edge (SIC = 15 %). Area for the mapping is north of 60° N (heavy black circle). Sectors selected for regional analysis are the Arctic Ocean (dashed magenta line), the Greenland/Norwegian Seas (green 1), the Barents Sea (green 2), and the Chukchi Sea (green 3).

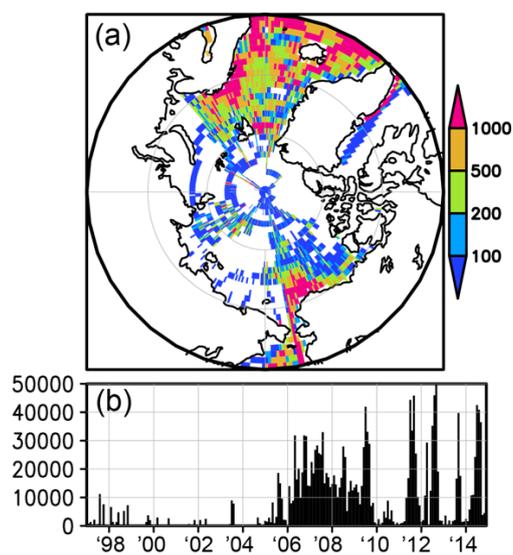

Figure 2: (a) The number of ocean surface CO₂ data in the grid boxes (1° × 1°) used in this study. Data are from SOCATv4, LDEOv2014, GLODAPv2, and collected by R/V *Mirai* of JAMSTEC between 1997 and 2014. (b) Monthly time series of the number of CO₂ data in the analysis area (north of 60° N).

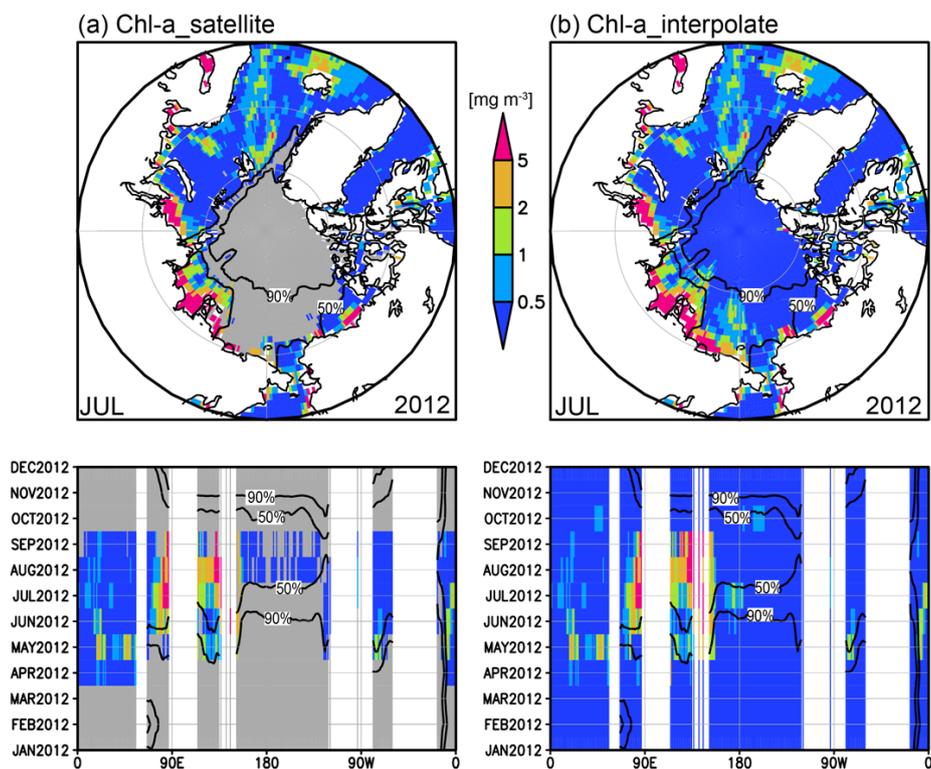

Figure 3: (a) Original and (b) interpolated Chl-a [mg m^{-3}] in July 2012 (upper panels), and along 75°N in 2012 (lower panels). Black lines denote SIC of 50% and 90%. Gray areas in (a) indicate missing Chl-a data.

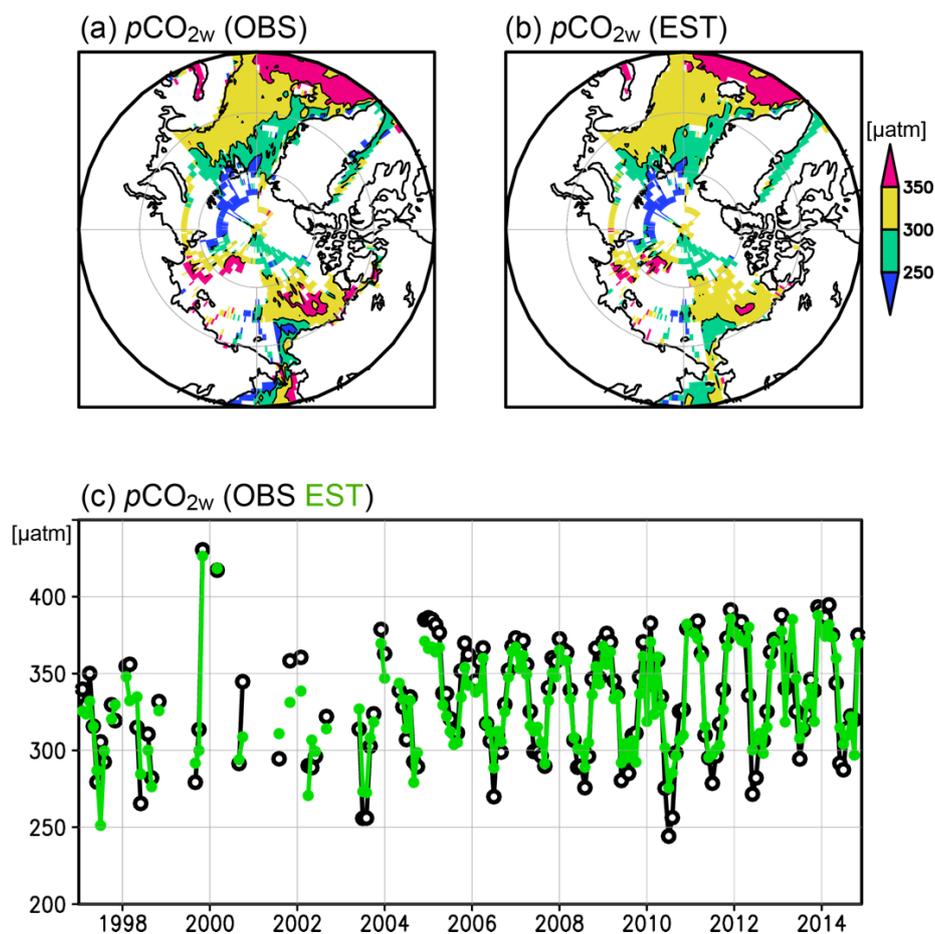

Figure 4: (a) Observed $p\text{CO}_{2w}$ averaged over the whole analysis period [μatm]. (b) Estimated $p\text{CO}_{2w}$ averaged over the grid boxes in which observed $p\text{CO}_{2w}$ values were available [μatm]. (c) Monthly time series of observed $p\text{CO}_{2w}$ averaged over the entire analysis area (black), and estimated $p\text{CO}_{2w}$ averaged over the grid boxes in which observed $p\text{CO}_{2w}$ values were available (green) [μatm].

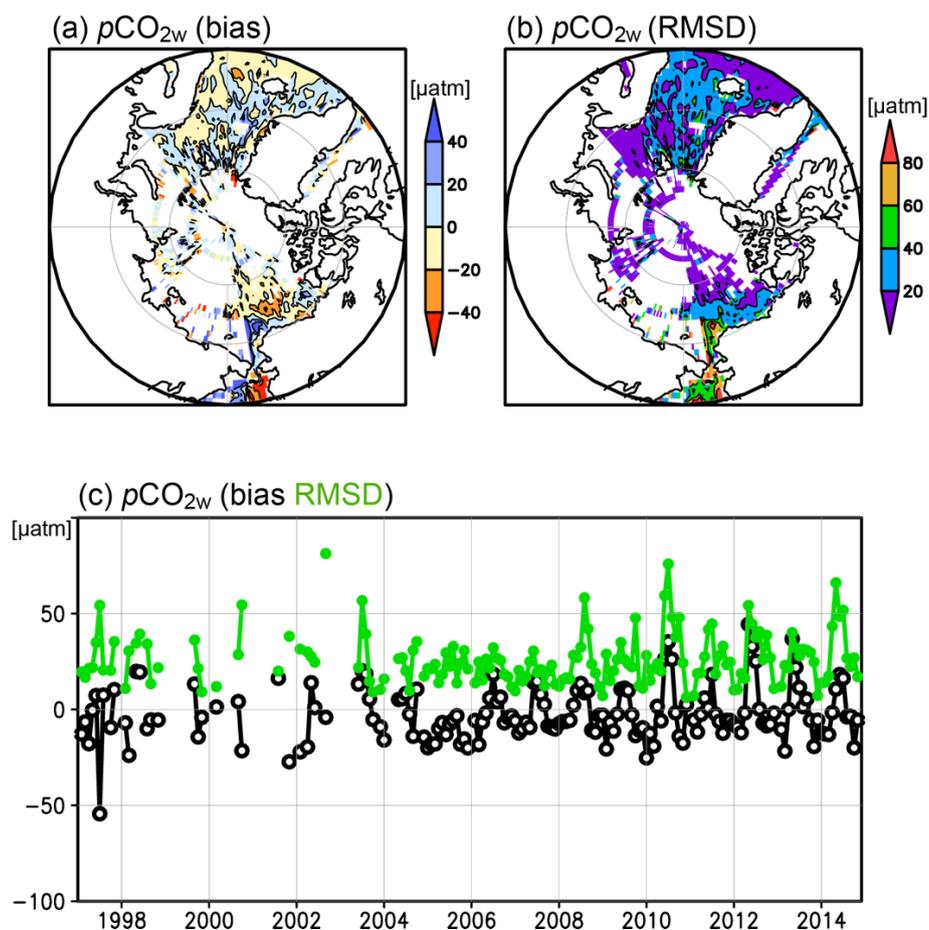

Figure 5: (a) Bias (estimate–observation) and (b) root-mean-square-difference between observed and estimated $p\text{CO}_{2w}$ averaged over the whole analysis period [μatm]. (c) Bias (estimate–observation; black) and root-mean-square-difference (green) between observed and estimated $p\text{CO}_{2w}$ averaged over the entire analysis area [μatm].

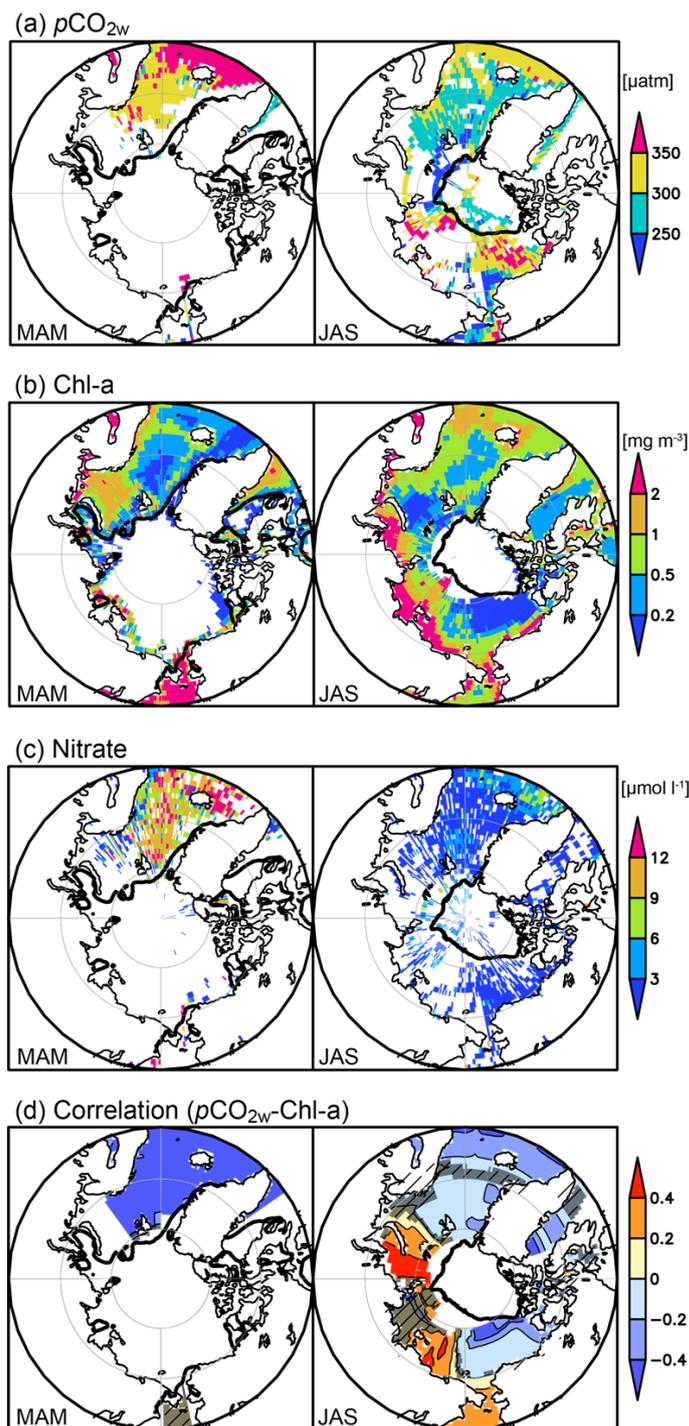

Figure 6: (a) Observed $p\text{CO}_{2w}$ [μatm], (b) non-interpolated Chl-a [mg m^{-3}] and (c) surface nitrate concentration [$\mu\text{mol l}^{-1}$] in March–May (left), and July–September (right) from 1997 to 2014. (d) Spatial correlation (correlation coefficient, r) between $p\text{CO}_{2w}$ and Chl-a in a window size of ± 1 month, $\pm 5^\circ$ of latitude, and $\pm 30^\circ$ of longitude in March–May (left), and July–September (right). Darker hatched areas represent values in grids where correlations are insignificant ($P > 0.05$).

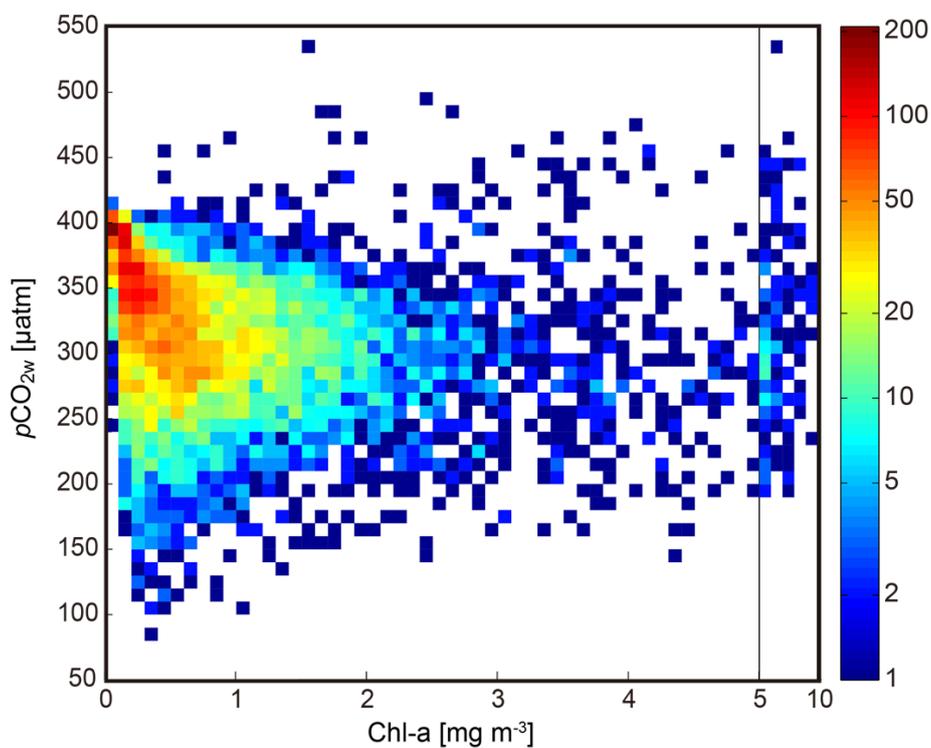

Figure 7: Observed $p\text{CO}_{2w}$ [μatm] vs. satellite Chl-a [mg m^{-3}] in the Arctic Ocean and its adjacent seas (north of 60°N) from 1997 to 2014. Colors indicate the number of data pairs in a $0.1 \text{ mg m}^{-3} \times 5 \mu\text{atm}$ bin when $\text{Chl-a} \leq 5 \text{ mg m}^{-3}$, or in a $1 \text{ mg m}^{-3} \times 5 \mu\text{atm}$ bin when $\text{Chl-a} > 5 \text{ mg m}^{-3}$.

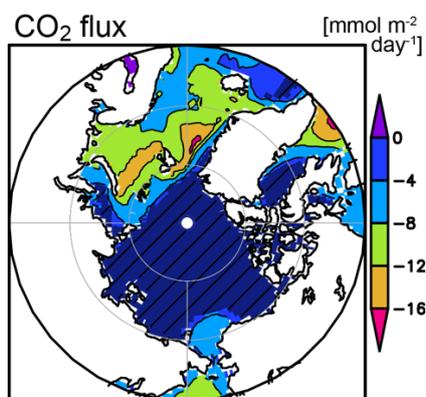

Figure 8: Eighteen-year annual means of CO₂ flux [mmol m⁻² day⁻¹] (negative values indicate flux into the ocean). Darker hatched areas represent show values in grids where fluxes were smaller than the uncertainty, estimated as described in the text.

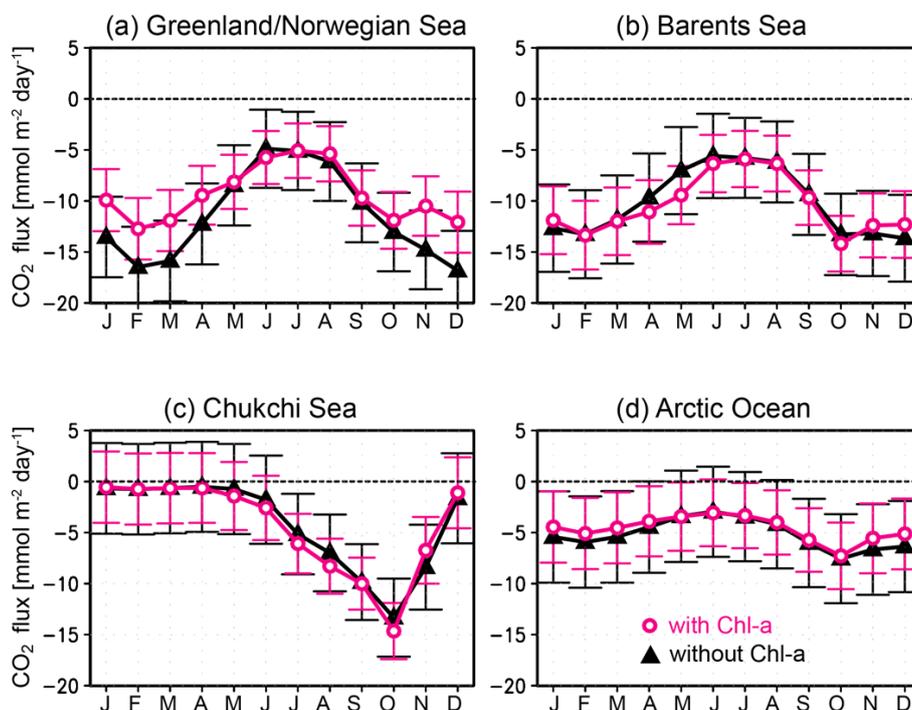

Figure 9: Eighteen-year monthly mean CO₂ flux [mmol m⁻² day⁻¹] averaged over (a) the Greenland/Norwegian Seas, (b) the Barents Sea, (c) the Chukchi Sea, and (d) the Arctic Ocean. Black lines with triangles show estimates without Chl-a by Yasunaka et al. (2016); magenta lines with open circles show estimates with Chl-a. Error bars show the uncertainty, estimated as described in the text.

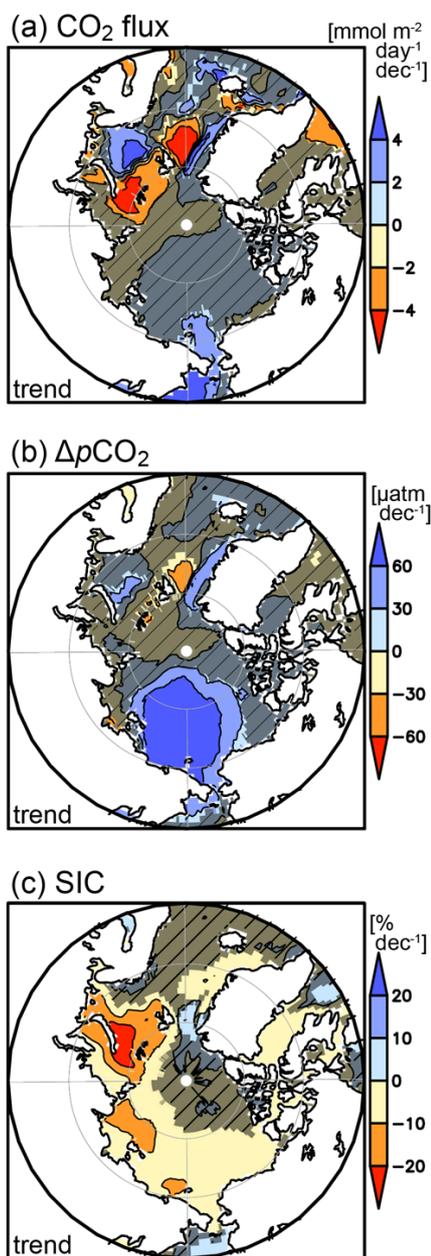

Figure 10: Trends in (a) CO₂ flux [mmol m⁻² day⁻¹ decade⁻¹], (b) ΔpCO₂ [μatm decade⁻¹], and (c) SIC [% decade⁻¹]. Darker hatched areas represent values in grids where trend values were less than the uncertainty, estimated as described in the text.

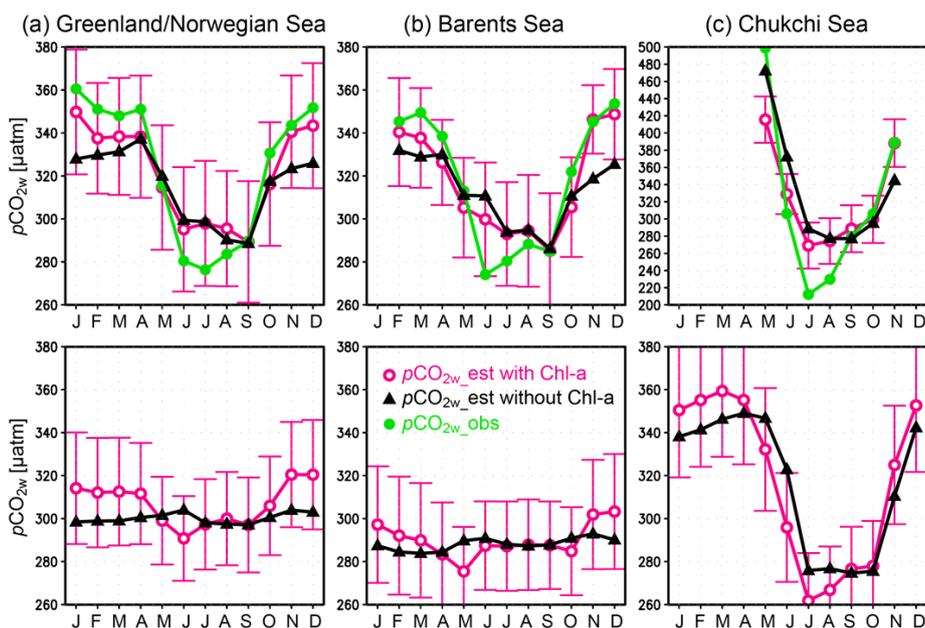

Figure 11: Eighteen-year averaged $p\text{CO}_{2w}$ seasonal variations [μatm] in (a) the Greenland/Norwegian Seas, (b) the Barents Sea, and (c) the Chukchi Sea. Black lines with triangles show estimates without Chl-a; magenta lines with open circles show estimates with Chl-a; green lines with closed circles show observed values. The upper panels show $p\text{CO}_{2w}$ averaged over the grid boxes in which observed $p\text{CO}_{2w}$ values were available, and the lower panels show $p\text{CO}_{2w}$ averaged for all grid cells with each region. Error bars show the uncertainty, estimated as described in the text.

Table 1: RMSD [mg m^{-3}] and correlation (r) between Chl-a values

	standard algorithm		coastal algorithm	
	RMSD	r	RMSD	r
Chl-a from Arctic algorithm	0.80	0.90	0.81	0.87
Interpolated Chl-a from Arctic algorithm	0.37	0.92	0.48	0.86
